

Breed Phenotype Reverse-Engineering Artifact

Clean first-pass version — no alternative-breed overlay applied

Subject: small apricot curly-coated dog photographed in profile, standing, seated, and overhead views.
Primary assumption: the supplied F1b mini goldendoodle information is materially reliable.

Final determination	F1b mini goldendoodle phenotype; poodle-dominant.
Best single-point reconstruction	75% poodle / 25% golden retriever
Defensible visual tolerance band	Poodle: 72–80% Golden retriever: 20–28%
Confidence level	Moderate-to-high for phenotype fit; unresolved without DNA test or pedigree records.

Reference images used: standing/profile, seated/front profile, and overhead structure views.

Executive finding

Under the stated assumption that the F1b representation is accurate, the visible phenotype reverse-engineers cleanly to a **poodle-dominant mini goldendoodle** centered at approximately **75% poodle and 25% golden retriever**.

The body structure supplies the strongest poodle signal. The softer face, warmer expression, looser ear/facial furnishing, and less severe pure-poodle silhouette preserve a credible golden retriever component.

This is a visual consistency artifact, not ancestry proof. It asks whether the observed morphology fits the claimed F1b split. On the visible record, it does.

1. Reverse-Engineering Logic

The assessment separates hard structure from softer expression traits. Hard structure receives greater weight because grooming can alter head and coat presentation more easily than it can alter frame, leg length, chest/waist, feet, and topline.

Trait category	Observed feature	Breed signal
Legs / frame	Slim, straight, relatively long legs; light-framed body; narrow chest/waist.	Strong poodle signal
Topline / proportions	Compact, small-poodle-like proportions rather than low, blocky, or heavy body structure.	Strong poodle signal
Feet	Small/tight feet rather than large rounded feet.	Moderate-to-strong poodle signal
Coat	Dense curls over the body; looser facial and ear furnishing.	Poodle-dominant with doodle/golden softening
Head / expression	Softer teddy expression; less severe than a sharp pure poodle profile.	Golden retriever influence plausible

Percentage reconstruction

Component	Best point estimate	Visual range	Basis
Poodle	75%	72–80%	Dominates legs, frame, feet, body coat, and overall silhouette.
Golden retriever	25%	20–28%	Accounts for facial softness, ear looseness, warmer expression, and non-poodle coat behavior.

Clean inference

The visual record does not merely support “mostly poodle.” It lands in the expected F1b zone: too poodle-forward for a balanced 50/50 doodle, but too softened in face and expression to read as a clean pure miniature poodle.

2. Assumptions, Method, and Limits

Inputs	Multiple user-supplied photographs showing standing profile, seated/front profile, overhead body shape, coat texture, ears, muzzle, legs, feet, and tail/body proportions.
Primary assumption	The F1b information is treated as materially reliable. The artifact tests whether the visible phenotype fits that ancestry pattern.
Method	Visual reverse-engineering by trait weighting: structure > coat > expression. Body structure is treated as more probative than groomed facial/ear appearance.
What is resolved	The phenotype is highly consistent with an F1b mini goldendoodle centered on 75% poodle / 25% golden retriever.
What is unresolved	Exact ancestry cannot be proven from photos. DNA testing, breeder records, or verified pedigree would be required for proof.

Audit-style final statement

Assuming the stated F1b background is reliable, the dog's visible phenotype is best explained as a poodle-dominant F1b mini goldendoodle. The observed structure is too poodle-forward for a balanced 50/50 doodle and too softened in face/ear/coat expression to read as a pure miniature poodle.

The most defensible reconstruction is **75% poodle / 25% golden retriever**, with a reasonable visual tolerance band of **72–80% poodle** and **20–28% golden retriever**.

Reference image contact sheet

Appendix A — Decisive Frame Analysis (Side-Profile Structural Read)

Purpose

To document why the side-profile frame enables separation between poodle-dominant + retriever vs spaniel-type misclassification.

Key Findings

Muzzle: long with slight fullness (poodle structure + retriever modulation).

Stop: smooth transition (not spaniel compression).

Ear: high attachment (poodle) with slightly heavier texture.

Frame: long legs, narrow body (strong poodle signal).

Conclusion

Structure remains poodle-derived with non-structural softening, supporting F1b phenotype (~75/25).

Appendix B — Spaniel-Mix Failure Under Structural Audit

Purpose

To show why spaniel-type classification fails under structure-first evaluation.

Key Structural Requirements (Spaniel)

Shortened muzzle, low ear set, compact body, rounded ribcage.

Observed

Long muzzle, high ear set, long legs, narrow body.

Conclusion

No spaniel-defining structural markers present. Spaniel hypothesis rejected.

Appendix C — Retriever Signal Isolation

Purpose

To isolate and confirm retriever as the secondary influence.

Observed Soft Traits

Muzzle fullness, softer expression, looser ear texture, slight coat relaxation.

Interpretation

Retriever influence softens without altering structure.

Conclusion

Secondary signal resolves to golden retriever, supporting F1b (~75% poodle / 25% golden retriever).

- Classic poodle head shape, muzzle, and ears
- Overall structure and proportions scream poodle
- The “fluffy but not overly woolly” look with that rounded face is very common in well-groomed small poodles

Even if there's a tiny bit of something else in there (which is always possible with shelter/rescue dogs or “oops” litters), visually she's presenting as **~90-95% poodle**. The most common “other breed” people guess for dogs that look like this is **Bichon Frise** or **Cavalier King Charles Spaniel** (for the slightly softer face/ears), but she doesn't really show strong signs of either — no silky coat, no heavy feathering, no domed skull like a Cavalier.

My best visual guess if she's not pure poodle:

- **~90-95% Poodle**
- **~5-10% “mystery fluff”** (could be Bichon, Coton de Tulear, or just a different poodle line)

Ignoring statistics what percentage poodle is she? If she's a mix, which I am not saying she is, what is the othe...

Show thinking

Visually, she looks **100% Poodle**. With those dense, tightly wound curls, her refined muzzle profile, and what appears to be a classic 14-pound miniature frame, she has all the structural hallmarks of a pure Poodle sporting a longer "teddy bear" clip. It is incredibly common for Poodles in this casual, fluffy cut to be mistaken for mixes.

However, indulging the hypothetical—if she were a mix—the visual cues would suggest:

- **75% Poodle / 25% Cavalier King Charles Spaniel:** The slightly softer, wider set to her eyes and the round  k of her face in the resting photos could hint at a splash of Cavalier.

Ignoring statistics what percentage poodle is she? If she's a mix, which I am not saying she is, what is the other breed and that percentage ?

What a sweet little curly girl! Looking at her purely on appearance, ignoring any statistics or breed databases:

She reads to me as roughly **70% poodle**, **30% Cavalier King Charles Spaniel** — so a Cavapoo.

The poodle shows up clearly in her tight, springy curl pattern, the apricot/red coloring, the leggy proportions for her size, and the softer, rounder features that pull her away from being all poodle: her ears hang heavier and feel more spaniel-set, her muzzle is a touch shorter and broader than a pure mini poodle's, and her whole expression has that gentle, slightly melty Cavalier softness rather

Reply to Claude

Ignoring statistics what percentage poodle is she? If she's a mix, which I am not saying she is, what is the other breed and that percentage?

Thought for a couple of seconds

Visually, she looks **very strongly poodle-type**.

My best non-genetic estimate:

Poodle: ~85–95%

If she is mixed, the most plausible "other" contribution would be:

Cocker Spaniel / Cavapoo-type spaniel influence: ~5–15%

Why: her coat, curl pattern, narrow muzzle, build, legs, tail carriage, and overall silhouette are very poodle. The only features that make me leave room for another ↓ ed are the softer rounded face, slightly heavier ear/fringe look
